Boolean Models

- Statistical Retrieval Models
 - Vector Space Models

Probabilistic Models (next following lecture)

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 2/31

Retrieval Models

- Retrieval Models are the theories about **relevance**
- Retrieval models provide a mathematical framework for defining the search process
- Relevance is a complex concept based on various assumptions

In document search engine, a document is **relevant** if it is one that the user perceives as <u>containing</u> information of value with respect to their personal information need

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 3/31

Boolean Retrieval Model

- Simplest form of ranking
 - ▶ e.g., apple AND store
- Query usually in **Boolean Logic expression**.
- Two possible outcomes: TRUE or FALSE
- The result is the *unordered* set of documents.
- "Exact-match" retrieval

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 4/31

Boolean Operators — Apache Examples

Operator	Description
OR	either terms should exist anywhere in the text
AND	both terms should exist anywhere in the text
+	the term after '+' should exist in the text
NOT	excludes documents that contain the term after 'NOT'
-	equivalent to NOT
~	returns documents that contain all the terms within a specific distance

Query Returns

Query	Returns
Apple	Documents which contain the term 'Apple'
Apple Store	Documents which contain either terms
Apple AND Store	All documents which contain both terms
+Apple Store	Documents which must contain 'Apple' and may contain 'Store'
Apple NOT "Apple Store"	Documents that contain 'Apple' but not 'Apple Store'
(Apple Store)~5	All documents which contain both terms within a specific distance

Boolean Search — Pros and Cons

Advantages

- Intuitive and explainable results
- Other types of feature (other than word existence) can be easily incorporated
- Efficient searching process, why?

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 7/31

Boolean Search — Cons

Disadvantages

- Rather stricter set theory rules are applied
 - a document can be either relevant or irrelevant; there's no 'somewhat' relevant
 - ▶ Boolean queries often result in either too few (=0) or too many (1000s) results.
- The importance of a token is neglected
- Less flexibility to express the users' information needs
 - Users should know how to build a query using the Boolean operators

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 8/31

Ranked Retrieval Models (vs. Set-based Models)

Set-theoretic Models	Ranked Retrieval Models
set of "relevant" documents query as a boolean expression	list of documents ordered by relevance free-text query
large set of relevant documents	top $k \approx 10$ relevant documents

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 9/31

Scoring Documents

- Measure how much information a document contains w.r.t. the user's information need
- Assign a score (e.g., [0-1]) to each document
- This score measures how well document and query "match".
- We need to model the scoring function.

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 10/31

Take 1: Jaccard Coefficient

- Used for gauging the similarity and diversity of sample set
- In *document-query matching* scenario, the elements are the tokens
- Alwasy assigns a score between 0 and 1

$$J(A,B) = \frac{|A \cap B|}{|A \cup B|}$$
$$J(A,A) = 1$$
$$J(A,B) = 0 \text{ if } A \cap B = \emptyset$$

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 11/31

Scoring example using Jaccard Coefficient

- query: Connect phone to car
- document 1: connect your phone via Android apps to your car display
- document 2: Cactus Car Wash Marietta was voted the best car wash in town

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 12/31

Issues with Jaccard for scoring

- Term Frequency is not considered
 - ► (In IR, *frequency* means the count of a term)
 - Rare terms in a collection are more informative than common terms.
 - ▶ However, a rare word is contributing the same to the score (*connect* vs. *to*)

How can we weight terms differently and normalize them for length?

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 13/31

Term Frequency, tf

- $tf_{t,d}$ of term t in document d denotes the number of times that t occur in d.
- We want to use tf in computing document-query match scores.
- Assumptions on term informativeness:
 - A document with more occurrences of the term is more relevant to the query, and
 - 2 Rare terms are more informative.
- Note, Relevance does not increase proportionally with term frequency.

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 14/31

tf Normalization

• We need to normalize the raw occurrence counts of a term for length

weighting scheme	tf weight
binary	0, 1
raw count	$f_{t,d}$
term frequency	$f_{t,d}/\sum_{t'\in d}f_{t',d}$
log normalization	$\log(1+f_{t,d})$
double normalization	$K + (1 - K) \frac{f_{t,d}}{\max_{\{t' \in d\}} f_{t'd}}$

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 15/31

Other Frequency Data

Collection vs. Document Frequency

- **Collection frequency** ($cf_{t,d}$) is the number of occurrences of t in the collection
- **Document frequency** ($df_{t,d}$) is the number of documents in which t occurs
- Usually, $df_{t,d} \propto cf_{d,f}$

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 16/31

Inverse Document Frequency, idf

- df_t is document frequency of t; the number of documents that contain t
- df_t is an inverse measure of the informativeness of t
- $df_t \leq |D|$ (document count)

$$idf(t,D) = \log \frac{|D|}{|\{d \in D : t \in d\}|}$$

• We use log to "dampen" the effect of *idf*

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 17/31

idf example, suppose |D| = 1M

$$idf(t,D) = \log \frac{|D|}{df_t} = \log \frac{|D|}{|\{d \in D : t \in d\}|}$$

term	df_t	idf_t
calpurnia	1	6
animal	100	4
sunday	1,000	3
fly	10,000	2
under	100,000	1
the	1,000,000	0

Note, there is one *idf* value for each term *i* in a collection.

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 18/31

TF.IDF

- Most fundamental, best known term weighting scheme
- The tf-idf weight of a term is the product of its tf weight and its idf weight.
- **tf** reflects the importance of the term *t* in a single document *d*.
- **idf** reflects the relative importance of the term *t* over the document collection *D*.

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 19/31

Effect of idf on Ranking

- Does idf have an effect on ranking for one-term queries, like "iPhone"
- idf has no effect on ranking one term queries
 - idf affects the ranking of documents for queries with at least two terms
- For the query *capricious person*, idf weighting makes occurrences of *capricious* count for much more in the final document ranking than occurrences of *person*.

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 20/31

Variants of tf and idf

Variants of term frequency (tf) weight

· · · · · · · · · · · · · · · · · · ·			
weighting scheme	tf weight		
binary	0, 1		
raw count	$f_{t,d}$		
term frequency	$\left f_{t,d} \middle/ \sum_{t' \in d} f_{t',d} ight $		
log normalization	$\log(1+f_{t,d})$		
double normalization 0.5	$0.5 + 0.5 \cdot rac{f_{t,d}}{\max_{\{t' \in d\}} f_{t',d}}$		
double normalization K	$K+(1-K)\frac{f_{t,d}}{\max_{\{t'\in d\}}f_{t',d}}$		

Variants of inverse document frequency (idf) weight

, , , , ,				
weighting scheme	idf weight ($n_t = \{d \in D : t \in d\} $)			
unary	1			
inverse document frequency	$\log rac{N}{n_t} = -\log rac{n_t}{N}$			
inverse document frequency smooth	$\log\!\left(\frac{N}{1+n_t}\right)+1$			
inverse document frequency max	$\log\!\left(rac{\max_{\{t'\in d\}}n_{t'}}{1+n_t} ight)$			
probabilistic inverse document frequency	$\log rac{N-n_t}{n_t}$			

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 21/31

Practical scoring function in Lucene

$$score(q, d) = \sum_{t \in q} \left(t f_{t,d} \cdot i d f_t^2 \cdot t.getBoost() \cdot norm(t, d) \right)$$

- $tf_{t,d} = \sqrt{f_{t,d}}$
- $idf(t,D) = 1 + \log\left(\frac{|D|+1}{df_t+1}\right)$
- t.getBoost() is a search time boost of term *t* in the query *q* as specified in the query text
- norm(t,d) is an index-time boost factor that solely depends on the number of tokens of this field in the document.

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 22/31

Term Weighting

binary (existence) \Rightarrow count (occurrence) \Rightarrow term weight

	a	able	about	academic	access	according	account	
D1	0.01	0	0.04	0	0	0	0	
D2	0.02	0	0.04	0	0	0	0.64	
D3	0.01	0.12	0	0	0	0	0	
D4	0.03	0	0	0	2.51	0	0	
D5	0.005	0.01	0.02	6.12	4.72	0.41	0	

Each document is now represented by a real-valued vector of tf-idf weights $\in \mathbb{R}^{|V|}$.

Boolean Models

- Statistical Retrieval Models
 - Vector Space Models

Probabilistic Models (next following lecture)

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 24/31

Vector Space Models (VSM)

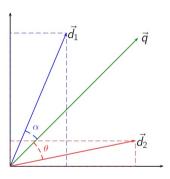

Documents (also queries) as vectors

- A document can be represented by a point in a |V|-dimensional vector space, where terms are the axes of the space.
- The vector space is *very* high dimensional.
- The document representations are sparse vectors Most entries are zeros.

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 25/31

Formalizing Vector Space Proximity

- Distance between two points (the end points of two vectors)
- Why is Euclidean distance bad?
- Use angle instead of distance
- Key idea: rank documents based on their angular relationship with the query.

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 26/31

Length Normalization

A vector can be (length-) normalized by dividing each of its components by its length – for this we use the L2 norm:

$$\|\vec{x}\|_2 = \sqrt{\sum_i x_i^2}$$

- Dividing a vector by its L2 norm makes it a unit (length) vector (on surface of unit hypersphere).
- Effect on the two documents d and d' (d appended to itself): they have identical vectors after length-normalization.
- Long and short documents now have comparable weights.

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 27/31

Cosine Similarity

Cosine similarity is a measure to compute the angle between two vectors, which can be used to compare the vector representations for documents/query. Let x and y be two vectors for comparison, such that $x = (x_1, x_2, ..., x_t)$ and $y = (y_1, y_2, ..., y_t)$ and θ is the angle between the two vectors,

$$\cos \theta = \frac{x \cdot y}{\|x\| \|y\|}$$

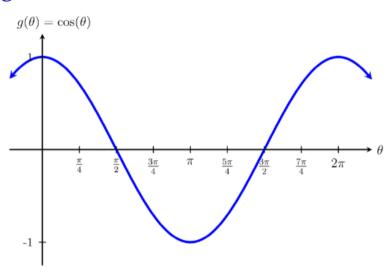

$$= \frac{\sum_{j=1}^{t} x_j \cdot y_j}{\sqrt{\sum_{j=1}^{t} x_j^2 \cdot \sum_{j=1}^{t} y_j^2}}$$

 $x \cdot y$ is the dot product of x and y, and ||x|| is the Euclidean norm of x

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 28/31

From Angle to Cosine

Jiho Noh (CS/KSU) Retrieval Models 1 Summer 2025 29/31

General Idea of Cosine Similarity-based Document Search

- Document d is represented as a vector \vec{d} in the vector space
- Query *q* is represented as a vector in the same vector space
- The cosine similarity between the document vector and the query vector is computed
- High cosine similarity indicates a strong match between the document and the query

Issues:

- It does not consider the order of terms in the document
- It depends heavily on the representation method of the document and query vectors
